

Connectivism

About connectivism

Connectivism¹⁾ is a new learning paradigm and a learning theory introduced in 2004 by [George Siemens](#)²⁾. This theory attempts to approach learning and knowledge in context of technological development during the last few decades, since the impact of technological achievements on learning and knowledge cannot be ignored.

Motivation for introduction of connectivism comes from notion that learning theories in frames of [behaviorism](#), [cognitivism](#), [constructivism](#) and [humanism](#) promote the understanding that learning occurs only inside a person. According to Siemens,

- *“These theories do not address **learning that occurs outside of people** (i.e. learning that is stored and manipulated by technology). They also fail to describe how learning happens within organizations... We can no longer personally experience and acquire learning that we need to act. We derive our competence from **forming connections**.³⁾”*

Siemens' connectivism incorporates ideas from:

- **Chaos theory** - Recognizing complex patterns and deep sensitivity on small changes in initial conditions are important properties of learning and decision-making as well as key aspects of chaos theory.
- **Self-organization** - This term usually refers to *“the spontaneous formation of well organized structures, patterns, or behaviors, from random initial conditions.”*⁴⁾ Self-organization is according to Siemens a characteristic of knowledge on personal as well as on institutional or corporate level.
- **Networks** - Network models were acquired because of their applicability and simplicity. Networks are sets of relations between elements which integrate those elements into a whole.

Connectivism integrates these principles. Learning is defined as **actionable knowledge** which can reside in a person but also outside one, for example in a database or an organization. The process of learning is focused not on acquiring more knowledge into or from each of such information sources, but on **connecting** them **and maintaining those connections**. Connection forming is important since the body of **knowledge is nowadays rapidly changing** and the common approach of a structured course in which packed knowledge is transferred to students is not efficient anymore. It serves institutions, but not students.

Connections are formed between nodes, but also between networks of nodes. Nodes can represent virtually anything, like a community or an individual, and the stronger the connection is, the faster information will flow between the nodes. Aggregated nodes form the network, but the network itself can only have limited influence on the nodes. According to Siemens⁵⁾, elements and characteristics of a network include:

- Content (data or information)
- Interaction (tentative connection forming)
- Static nodes (stable knowledge structure)
- Dynamic nodes (continually changing based on new data, since knowledge can and does change over time)

- Self-updating nodes (nodes tightly linked to original information source)
- Emotive elements (emotions that influence the prospect of connection)

Connections between the nodes can depend on various factors which make them stronger or weaker⁶⁾: motivation (impacts individuals determination to foster deeper connections), emotions (affect our evaluation of nodes and allow existence of contradictory perspectives), exposure (nodes grow and develop through forming connections to other nodes), patterning (recognizing the nature of different sources of information), logic and experience.

Keywords and most important names:

- [George Siemens](#), [Stephen Downes](#)

Criticisms

Connectivism is criticized for being more a pedagogical approach and a model rather than learning theory, since it doesn't really attempt to explain processes of how people learn.⁷⁾ It also describes learning as *actionable knowledge* emphasizing only the result, not the process of learning.

Lack of references to previous related works makes connectivisms contributions hard to identify.
